Description

The present invention relates to digital data message networks and the establishing of communication paths therein in which the communication path, or route, that a message takes through the network is computed dynamically, that is, the path is determined anew each time a communication session between two users of the network is attempted to be established.

Communication networks are arrangements of computers, communication controllers and associated peripheral equipment and links which allow "end users" located at remote locations in the network to establish and maintain communication of information. An end user in this context may be a human user at some type of terminal, or an application program running on a host computer or on some type of intelligent device controller (ie, workstation, personal computer, display controller, etc). Figure 1 illustrates a small communication network 10. In it, two IBM System 370 host computers 12, 14 and three IBM 3725 Communications Controllers 16, 18, 20 are interconnected, supporting five terminals 22, 24, 26, 28, 30 connected as shown. Communication links 32, 34, 46, 38, 40, 44, interconnect the computers 12, 14 and controllers 16, 18, 20 as shown.

Communication between, say, terminal 30 and host computer 12 in Figure 1 would be possible over several different paths. In order to visualise the communication in a network, a convention has been adopted in which the computers and communication controllers in a network are referred to collectively as nodes and the connections between nodes as links. End-user devices, whether displays, printers, etc are referred to collectively as terminals. Figure 2 depicts a node and link diagram of the network 10 shown in Figure 1, with like elements in Figure 2 having the same reference numerals as in Figure 1, but primed. Terminals are not shown in the diagram, since they are not directly involved in the communication establishment and control process to which the present invention is related.

A conversation, called a session, between an end user at terminal 30 and an application program in host computer 12 in Figure 1 would involve communication between nodes 12 and 18, or 12' and 18' in Figure 2. Several different paths are possible for such a session. For example, communication could be simply via link 34', or the path could involve links 32' and 40' and node 16'. Alternatively, the path could involve links 32', 36' and 38' and nodes 16' and 14'. The choices increase with the size and complexity of the network.

Except in very limited circumstances in which the network is fully connected, the information input at an origin node (supporting one end user) travels through one or more intermediate nodes before reaching the destination node (supporting the other end user). Information transmitted by one node and directed to another node must travel over the links interconnecting the nodes. In some networks, all information transmitted between two end users during a specific communication session traverses the same path, called in that case a route. The mechanism used to create the route, hereafter called the route mechanism, is dependent on a specific network architecture.

Most network routing mechanisms use routing tables in each node (origin, intermediate, and destination) to forward messages to the next node. Routing mechanisms may vary but several use an index into a routing table (the index being either a route identifier or a combination of source and/or destination node identifiers) to specify to which outbound link, and therefore to which next adjacent network node, the message is to be sent. Naturally when the message reaches the destination node, but is instead processed by the end user.

The routing tables in each network node can be established either statically or dynamically. In the static case, the routing definitions are fixed when network operating is started. The static mechanism is not relevant to the invention and will therefore not be discussed.

In dynamic routing, a route creation technique is employed that dynamically creates an end-to-end route, from the source node to a destination node, which can be used during a specific communication session. This end-to-end route remains defined and active until all sessions using the route terminate. Then the route can be eliminated to free network resources, such as routing table entries to be used for other dynamically created routes.

Several methods can be used to create dynamic routes within networks. One such method, disclosed in Proceedings of the Seventh International Conference on Computer Communication, Sydney, 30.10.-2.11.1984 Elsevier Pub., Amsterdam, NL; J.H. Jaffe et al.; "Applying dynamic routing for a general network architecture", pages 716-721, employs a topology data base which contains the identity of all physical nodes and links in the network, including their connectivity, status, and physical characteristics to build a route dynamically. This method selects appropriate nodes and links based on their recorded status and creates a message, hereafter called a ROUTE SETUP message, containing a list of the nodes and links to be used in the route. The ROUTE SETUP message traverses each node in the list, allowing each node to

build an entry in its routing table so that subsequent messages for a session assigned to the route can traverse the same physical nodes identified in the ROUTE-SETUP message. Both forward and backward pointers are placed in the node routing table.

Routing in communication networks is discussed by Jaffe et al in "SNA Routing: Past, Present and Possible Future" appearing in the IBM Systems Journal, Vol. 22, No 4 (1983), Tymes in "Routing and Flow Control in TYMNET" appearing in the IEEE Transactions on Communications, Vol. COM-29, No 4, (1981), and by McQuillan et al in "The New Routing Algorithm for ARPANET" appearing in the IEEE Transactions on Communications, Vol. COM-28, No 5, (1980).

Clearly, it is important for the topology data base to have current information as to which nodes and lines are available for communication. Otherwise, attempts might be made to create routes which have unavailable nodes or links, and several route creation attempts might be necessary before an available route is actually found. This represents an unnecessary waste of network resources. Other than by manual, operator input, the reporting of the initial status, failures and reactivations of the network nodes and links, hereafter called network elements, has been done by the broadcast of status changes by adjacent nodes. The Tymes and McQuillan et al articles mentioned above describe such broadcast update methods. These broadcast status updates have the advantage of not requiring operator intervention. However, they have the problem, especially in large and complex networks, of considerably increasing network overhead traffic. In some situations, it is preferable to accept less than perfect knowledge of the network status in order to reduce this overhead. In fact, it is necessary in such networks to have some mechanism to "kill" the broadcast message which propagates throughout the system, or else the message reverberates throughout the network forever. Typical mechanisms include the incorporation of a cutoff time, after which the message is discarded from the network. However, even with such limiting mechanisms, status update messages occupy a large proportion of the overall network message-handling capability, such that there is less capacity available for users messages.

Thus, it is apparent that there is a need for a means for updating a topology data base in a dynamic routing environment such that there are significantly reduced demands on the message handling capability of the network as compared with prior art schemes for updating topology data bases.

Accordingly, the present invention provides a digital data message transmission network comprising nodes connected by links, wherein a message travels between a source node and a destination node along a route comprising a sequence of nodes and connecting links, said network including means for maintaining a topology data base recording the potentially available communication routes through the network and the status of the network nodes and links; each node being adapted to maintain a routing table and: when acting as a source node, obtain a route from the topology database and send a ROUTE SET-UP message along the route to thereby establish the route; respond to a ROUTE SET-UP message by recording an entry in its routing table with the identity of the route and the links and/or nodes therein that are immediately adjacent to that particular node; said network being characterised in that each node is further adapted to: detect any failure of an immediately adjacent node or link in the route either whilst attempting to establish the route or after the route has been established, and in response thereto (i) record the status of the route as inoperative in the respective entry in the node's routing table, said entry remaining substantially intact; and (ii) transmit a ROUTE FAILURE message identifying the failed node or link along the route in the opposite direction to the failed node or link; respond to a ROUTE FAILURE message by (i) forwarding said ROUTE FAILURE message along the route in said opposite direction; and by (ii) further recording the status of the route as inoperative in the respective entry in the node's routing table, said entry remaining substantially intact; and when acting as a source or destination node, additionally forward said ROUTE FAILURE message to the topology data base for updating the recorded status of the network nodes and links.

The present invention further provides a method of controlling a digital data message transmission network as set out in claim 5.

Such an arrangement greatly reduces the overall status message traffic in even a complex communication network by ensuring that only the specific nodes involved in the use of an element are informed of the current status of that element.

The present invention will be described further by way of example with reference to preferred embodiments of the invention, as illustrated in the accompanying drawings, in which:

- FIG. 1 is a block diagram of a simple mesh type communication network;
- FIG. 2 is a schematic representation of the network shown in FIG. 1;
- FIG. 3 is a schematic representation of a topology data base route table used by the network of Fig. 1;
- FIG. 4 is a schematic representation of a route statement;
- FIG. 5 is a schematic representation of a ROUTE REQUEST message;

FIG. 7 is a schematic representation of a ROUTE-SETUP message;

FIG. 8 is a schematic representation of a routing table;

FIG. 9 is a schematic representation of a ROUTE FAILURE message; and

FIG. 10 is a schematic representation of a network with a topology data base.

5 In the drawings, like elements are designated with similar reference numbers, and identical elements in different specific embodiments are designated by identical reference numbers.

The present invention incorporates a method and apparatus which can be used to dynamically report the status of the network nodes and links to topology data bases so that ROUTE-SETUP messages can be created efficiently with knowledge of the physical route element status. The description that follows is applicable to an IBM SNA network comprising, for example, IBM System 370 computers and IBM 3725
10 Communication Controllers as nodes, and suitable communication links for network interconnection. However, the principles and protocols are presented with sufficient generality to enable application to any communication network having dynamic routing that relies on one or more topology data bases for route creation, and local routing tables at each node for the establishment and maintenance of communication
15 sessions.

In the preferred embodiment, each topology data base is initially set up with information as to all of the nodes and links, and their potential connectivity to adjacent nodes. This information is entered by way of conventional input statements either interactively or via batch definitions. The link and node statements further specify certain characteristics, such as line(link) transmission speed, node buffer size, and element
20 data transmission security, which are used by end users to request a route. These characteristics are set forth below under RULES OF OPERATION, DEFINITIONS & STATES, part a) Data Types. Additionally, each network element in the topology data base is initially marked as "assumed operative", or available. This initial status has nothing to do with the actual status of the corresponding elements, but allows the route selection technique to select the element for a route setup attempt and dynamically ascertain its
25 actual operative or inoperative status via the feedback mechanism. The information is stored conventionally, in such a way as to be available for scanning and comparing when a route request is received.

This information is entered for 1) routes, 2) links, and 3) nodes. Thus, assuming the interactive input method (as opposed to batch), a route statement is used to enter information defining a route between two nodes between which communication is to be allowed. This statement specifies the links and nodes, in
30 order, in that route, and an identifier (ID) for that route. For each pair of nodes that may communicate, as many route statements as there are distinct routes between those nodes may be entered. Figure 3 illustrates the topology data base entries for the potential routes between nodes 16' and 14' in Figure 2. In this case there are three such routes: 50, 52, and 54. Figure 4 illustrates the form of a route statement 58. Link and node names 60 are placed in the sequence in which a message traverses that route, starting with
35 the origin node and ending with the destination node. The statement type 62 identifies the statement as a route statement.

Figure 5 illustrates a link statement 64 and a node statement 66, showing the various fields 68, 70 identifying the element and containing data for the aforementioned characteristics. The statement type 72, 74, identifies the statements as link or node statements, respectively. The information entered via the route,
40 link and node statements is conventionally stored in such a way as to be available for scanning and comparing when a route request is received, so as to, first, retrieve all routes identified between the specified end nodes, and, second, find the best match of characteristics for the elements in the selected routes against the specified characteristics and thereby select the best route.

When an end user desires to communicate with another end user, a session is requested of the control
45 program resident in the origin node. The session request includes the names of the source and destination nodes supporting the end users and a class of service. The class of service is a conventional shorthand for a set of the aforementioned characteristics of the route to be selected. In the preferred embodiment, the information in the session request is forwarded in a message, hereafter called a ROUTE REQUEST message, to the nearest available topology data base for the selection of a route. Figure 6 illustrates a
50 ROUTE REQUEST message 76. It comprises a request code 78, identifying the message as a ROUTE REQUEST, the origin node name 79, the destination node name 80, and the class of service name 82.

Upon receipt of the ROUTE REQUEST message, the topology data base selects a potential route whose elements conform to the characteristics identified in the specified class of service. If a route with the same exact set of elements is already in use with the same characteristics, the session will be assigned to
55 the already created route. If a route has not already been created, the topology data base is scanned to select the best route between the source and destination nodes, based on the match of actual element characteristics against the characteristics requested. Only nodes and links which are assumed or known to be operative can be selected in this process. The selected route is then described in a message containing

a list of nodes and links comprising the route, along with a unique route identifier (route ID) for that route, hereafter called a ROUTE-SETUP message. Figure 7 illustrates a ROUTE-SETUP message 84. The request code 86 identifies the message as a ROUTE-SETUP message. The route ID 87 identifies the route. The node names and link names 88 appear in the sequence a message travels on the route, as in the route statement 58 (Figure 4, supra).

Route elements are assumed initially to be operative, because when the topology data base is activated, the status of each network element is unknown. Rather than initially obtaining the status of each element defined in the topology data base through operator input, exchanges with other data bases, or queries of each network element, the status is learned as sessions are requested by using the preferred embodiment of the present invention herein described.

As the ROUTE-SETUP message traverses the network, each active node creates routing table entries in conventional fashion for both directions of the communication. That is, when the ROUTE-SETUP message is processed, an entry is made in the routing table, containing the route ID (including origin and destination node names or addresses) and the outbound link address. As is known, this permits quick routing of messages thereafter via the route ID accompanying the message. When a message arrives with this information, a simple table scan yields the outbound link address, which is sufficient for sending the message on its way.

In an alternative embodiment, the route ID is reduced to a single Local Path Identifier (LPID) in each node, which may be a sequentially selected number starting with zero that is assigned to a route as the ROUTE-SETUP message for that route arrives. The LPID is entered into the table, and sent back to the previous node for entry into that node's routing table. Each routing table, in this embodiment, has the LPID it assigns, the outbound link to the next node, and the LPID assigned by the next node in the route. When a message arrives at a node in this embodiment, the LPID for that node is extracted from the header and used to locate the table entry for that session. The next node's LPID, located in the table, is then exchanged for the incoming LPID. The message is then sent on to the next node via the assigned outbound link, and so forth. Figure 8 illustrates a routing table 90 including a unidirectional entry 88 for a hypothetical route, using the LPID method. As shown, there are three elements to an entry, an LPID 94, the outbound link ID 96, and the LPID for the next node 98.

After the information necessary for the routing table entry is extracted from the ROUTE-SETUP message, it is sent on to the next element, and so on, to create all of the necessary table entries for the route. If all nodes and links in the end-to-end route are active, the ROUTE-SETUP will be successful and an end-to-end route will be created.

Each routing table entry in each node traversed is marked as operative. If a node cannot forward the ROUTE-SETUP message to the next node because either the link to that node or the node itself is inoperative, then a ROUTE FAILURE message identifying the inoperative link or node is generated and returned to the route origin for forwarding to the topology data base. The inoperative status is marked in the topology data base and that network element is not used in subsequent ROUTE-SETUP messages until its status changes.

As the ROUTE FAILURE message returns through each node identified in the ROUTE-SETUP, each node's routing table entry remains intact, with the status of the route being marked as inoperative. These table entries are used for the feedback mechanism to the end node (and its topology data base) when the failed element is re-activated. The ROUTE FAILURE message is transmitted by following the node routing table entries set up from the failed ROUTE-SETUP message. Figure 9 illustrates a ROUTE FAILURE message 100 for an LPID-based network. It includes a Request Code 102 identifying the message as a ROUTE FAILURE message, the node ID of the node detecting the failure 104, Failed Element ID 106, and Next LPID 108.

When the node that reported the ROUTE FAILURE (the "adjacent node" detects that the inoperative element subsequently has become operative, a ROUTE ELEMENT OPERATIVE message is created and sent to the origin node for forwarding to its topology data base. The topology data base then resets that element's status entry to operative. The element is then available for subsequent ROUTE-SETUP attempts. The ROUTE ELEMENT OPERATIVE message is identical to a ROUTE FAILURE message (100, Fig. 9), except that the Request Code identifies it as a ROUTE ELEMENT OPERATIVE message.

If more than one route had attempted to use the inoperative element, more than one set of routing table entries would have been created in the adjacent node and for as many of those sets of entries as had been created. ROUTE ELEMENT OPERATIVE messages would be created and sent back to the corresponding origin nodes for resetting of their topology data base entries for that element to operative.

This notification flows to the route origin node by following the node routing table entries set up from the failed ROUTE-SETUP message, in the same manner as the ROUTE FAILURE message.

The same process is used after an end-to-end route is successfully established and a failure occurs on a link or node in the route. The same ROUTE FAILURE message is returned, in this case to both end nodes, the origin and the destination node, for forwarding to the topology data base of each end node. The ROUTE FAILURE message identifies the failing element, and as in the initial case of failure to set up the route, the routing table entries in the route segments to the end nodes remain intact as the message travels back to the end node. As in the previous case, when the failed element becomes operative, the node routing table entries are used by ROUTE ELEMENT OPERATIVE messages (one in each direction around the point of failure) to follow the route back to the end node for forwarding to the topology data base(s) to indicate the operative status of the network element.

In either case, as the ROUTE ELEMENT OPERATIVE messages flow to the topology data base(s), the routing table entries are removed from the nodes along the route to recover the routing table space just as if the end-to-end route were being normally deleted after the termination of all sessions using the route.

The feedback mechanism functions in the face of both single point and multiple point failures along the route, as described in greater detail below.

The basic elements of the feedback mechanism of the preferred embodiment can be described by a set of rules, definitions, states and protocols which may be applied to any communication network having dynamic routing of the type herein described. The protocols are described in four operational cases.

RULES OF OPERATION, DEFINITIONS & STATES

1. Topology Data Base. There will exist one or more topology data bases which contain network node, connectivity and status data which can be used to select and end-to-end route through a communication network.

For each route element (that is, for each network node, which can be either source, destination, or intermediate node host or communication processor; and for each link, which can be either teleprocessing link, channel connection, local teleprocessing loop, Local Area Network, fibre optic line, or any other medium which can connect two host or communication processor nodes), there exists a set of parameters as follows:

<u>Element</u>	<u>Identifiers</u>	<u>Connectivity</u>	<u>Characteristics</u>	<u>Status</u>
Node	Node Name Node Address	Adjacent nodes	Message Storage	Operative
			Capacity	Inoperative
			Processing Power	Unknown/
			Security	(Assumed Operative)
Link	Link Name Link Address	Adjacent nodes	Bandwidth	Operative
			Reliability	Inoperative
			Security	Unknown/ (Assumed Operative)

These characteristics are well known in the art.

Various methods can be utilised to create the entries and element knowledge in the topology data base. They include operator input, a system generation process, automatic element identification at element activation, etc.

2. Route Selection Algorithm. The algorithm(s) utilised to select a route (ie, secure, least delay, greatest bandwidth, etc) should not affect the operability of the invention in a network, provided the selection algorithm adheres to the rules for creation of the selected route list and element status described above.

3. Route Request Mechanism. A mechanism is provided to allow a user to request an end-to-end route from source to destination nodes through the network. This request is sent to a topology data base with

an indication as to the characteristics (secure, least delay, etc) desired. The request initiates the route selection process in the topology data base and creates a ROUTE-SETUP message.

4. ROUTE-SETUP Message. This is a message which contains the list of nodes and links selected to create the end-to-end route from source to destination nodes. The ROUTE-SETUP message traverses the network, from the source to the destination, node to link to node to link, etc, in the order specified in the ROUTE-SETUP message. As it traverses the proposed route, routing tables are created in each node traversed, the forward and backward adjacent node connections being indicated by entries in the routing table. The ROUTE-SETUP can have one of two replies: ROUTE-SETUP-REPLY message or ROUTE-FAILURE message.

5. ROUTE-SETUP-REPLY Message This message is issued from the destination back to the source on a successful creation of a route.

6. The ROUTE FAILURE Message is returned for a failed ROUTE-SETUP attempt, and for the failure of an element in a successfully-created route. In the case of a failed ROUTE-SETUP attempt, when a network node cannot continue to forward the ROUTE-SETUP message to its neighbour, it creates a ROUTE-FAILURE message. This message, illustrated in Figure 9, is returned to the source to be forwarded to the topology data base. This ROUTE-FAILURE message indicates which node detected the inoperative network resource. The topology data base records the status of the inoperative element (ie, L3) and does not reuse this element for other ROUTE-SETUP attempts until subsequently informed that the element is operative by the ROUTE-ELEMENT-OPERATIVE message. In the case of the failure of an element on an established route, the same ROUTE-FAILURE message is created, and for the same purpose, but in this case, it is sent to both participating end nodes.

7. The ROUTE-ELEMENT-OPERATIVE Message is created by a node when it detects the reactivation of an inoperative element. The ROUTE-ELEMENT-OPERATIVE message is created and sent provided that a ROUTE-SETUP message has flowed prior to the element changing from inoperative to operative. The ROUTE-ELEMENT-OPERATIVE message traverses the network back to the origin node by using the routing table entries from the earlier ROUTE-SETUP MESSAGE.

8. ROUTE-DELETE Message. This message is sent on the route to signal that the route is no longer needed. It is created by the route end-points (either source or destination node) when all sessions assigned to a specific end-to-end route have ended. As the ROUTE-DELETE message traverses the network, each node in its path frees the routing table entries assigned to that specific route and forwards the message on the route being deleted. The ROUTE-DELETE message has no effect on the element status in the topology data base since this message only issues on active routes and the element status is not changed from their currently OPERATIVE state.

9. Resource State. Each element (node, link) can have three states: UNKNOWN-ASSUMED OPERATIVE (UNK), OPERATIVE (OP), or INOPERATIVE (INOP). If an element is in the OP or UNK state, it can be utilised for route selection purposes. In the INOP state, the element cannot be utilised for route selection until it is marked UNK or OP.

a) UNKNOWN-ASSUMED OPERATIVE STATE SETTING

- 1) All elements are considered UNK when the topology data base is activated, as is a new element when added to an already existing topology data base.
- 2) An element in the INOP state is changed to UNK if another element on the same INOP route but closer to the topology data base also fails. This is done to ensure that an element does not stay INOP indefinitely because a ROUTE-ELEMENT-OPERATIVE report could not reach the topology data base due to a second outage.

b) OPERATIVE STATE SETTING

- 1) elements change from UNK to OP when a ROUTE-SETUP-REPLY message is received.
- 2) Elements change from INOP to OP when an element which prevents the success of a ROUTE-SETUP request becomes operative, causing the generation of a ROUTE-ELEMENT-OPERATIVE message.

c) INOPERATIVE STATE SETTING

- 1) A ROUTE-FAILURE resulting from a ROUTE-SETUP attempt causes a state change to INOP for the identified inoperative element over which the ROUTE-SETUP could not be forwarded.
- 2) A ROUTE-FAILURE notification on an active route causes a state change to INOP for the identified

failed element.

10. Node Routing Tables.

Each network node contains a node routing table which is used to route messages through the network. The node routing table is constructed dynamically as required by routes, using the ROUTE-SETUP mechanism. Each entry consists of forward and backward pointers to the outbound queues associated with the "next leg" of the message journey in each direction as well as the status or state of the entry. If the node is the source or destination node for the route, this is also indicated in the table entry.

There are two states that each node routing table entry can have: OP or INOP. The OP state is set when the route is created. The INOP state is set by the following conditions:

- a) A ROUTE-FAILURE notification is returned from a ROUTE-SETUP attempt.
- b) A ROUTE FAILURE notification is received on an active route.

The state entry in the routing table can be used by an operator for information purposes (eg, operator enquiries), and by a node to cut off further messages on an established route that has a ROUTE FAILURE message propagating back to it, thus freeing valuable link time.

11. Protocols

The feedback mechanism of the preferred embodiment of the present invention incorporates certain protocols to ensure proper notification of the topology data base(s) about the status of resources on a dynamically created route within a network.

These protocols are described using four cases covering critical network events. They are:

- 1) The notification of the topology data base when a failed element (one in a previously used route) becomes reactivated.
- 2) The double failure case where two elements fail on an active or pending-active route.
- 3) The discovery of an inoperative element during a ROUTE-SETUP attempt.
- 4) The failure of an element in a pending-active route after the ROUTE-SETUP message has passed the failing link but before the ROUTE-SETUP-REPLY has been returned over the failing link.

Case 1: Route Failure and Subsequent Notification After Recovery

Assume that a dynamic route A-L1-B-L2-C-L3-D-L4-E has been created in the network 110 depicted in Figure 10 for a session between nodes A and E. In nodes A, B, C, D, and E the route table entry states are OP. Assume that a topology data base 112 was utilised, at node A, to choose the route elements comprising this route and that the states of all the network elements in the database are OP. The rules of operation are as follows, assuming a failure of link L2 and considering the processing at nodes B and A. The processing at nodes C and E would be similar.

- a) The failure of L2 is detected by both nodes B and C.
- b) In this example Node B creates a ROUTE-FAILURE message and sends it to Node A, for forwarding to its topology data base.
- c) As the ROUTE-FAILURE notification traverses the network to node A, the routing table entry for that route in each node in the direction away from the failed element (ie, B to A) is marked INOP but remains in the node routing table.
- d) The ROUTE-FAILURE notification causes the topology data base at A to mark the link L2 as INOP so that it is not subsequently used to initiate another ROUTE-SETUP attempt through L2.
- e) When link L2 becomes operative, node B searches its node routing table to find the entries which are marked INOP and which previously utilised L2 in their outbound path. Then node B creates ROUTE-ELEMENT-OPERATIVE messages for the routes corresponding to each such entry. In this example the ROUTE ELEMENT OPERATIVE message indicates that L2 is now OP and is transmitted along the route back to node A. Each node in the path, upon forwarding this ROUTE-ELEMENT-OPERATIVE message, deletes the route's existing INOP entry from its node routing table.
- f) When the ROUTE-ELEMENT-OPERATIVE message reaches node A, it is forwarded to the topology data base supporting Node A. The topology data base then updates its element status for L2 to OP so that L2 can be used for a new ROUTE-SETUP attempt.

Similar processing occurs in the opposite direction from node C to node E, including node D, and to the topology data base supporting node E if different from that of Node A.

CASE 2: DOUBLE FAILURE CASE

Consider the same network depicted in Figure 10. Assume again that a route was created from A to E through each node using L1, L2, L3 and L4. Consider the following events: first link L3 fails, then link L2 fails. The following will occur.

a) Node C detects L3 failure. Node C scans its node routing table and when it finds an entry with an outbound link of L3, it sends a ROUTE-FAILURE notification in the reverse direction (ie, to node B). The routing table entries in nodes C, B, and A are left in the routing tables but are marked INOP. At node A, the ROUTE-FAILURE message is given to the topology data base where the element entry for L3 is marked INOP. Similar processing is performed in the direction of node E and node D detects the L3 failure.

b) When, subsequently, node B detects L2 failure, it scans its node routing table, sends a ROUTE-FAILURE identifying L2 as failed to A using the operative part of what is known to be an already inoperative route. Node A forwards this notification to the topology data base. Both nodes A and B leave their routing table entries in the INOP state.

c) When the topology data base receives this second ROUTE-FAILURE notification for the same route, although for a different failed element, it scans its topology data base and marks the original failed element (L3) as UNK, unless L3 is known to be INOP because of its presence in another route, and marks the newly-failed element (L2) as INOP. At this point, several conditions can occur, dealing with the time at which L2 or L3 becomes operative. Each condition is described below.

1) Assume L2 becomes operative while L3 remains inoperative. When L2 becomes operative, node B uses the method described in Case 1 to notify the topology data base that L2 is now available. Also, the routing table entries in B and A are deleted. The topology data base then marks L2 as OP. A ROUTE-SETUP request can be sent to establish the route (assuming a session wants to use the route) and will fail at the L3 link.

The partially-constructed route segment will remain, awaiting L3's becoming operative again.

2) Assume L3 becomes operative but L2 does not. In this case, the topology data base does not get the notification since L2 is not operative and blocks the path to origin Node A. This does not cause problems, however, because the topology data base had assumed L3 was operative (ie, UNK) after L2 failed, anyway.

3) Assume L3 becomes operative, followed by L2 becoming operative. This is handled as in items (2) and (1) above except that now ROUTE-SETUP succeeds because L3 is operative. Processing of this double failure from the point of view of nodes D and E is similar to B and A except in the opposite direction. Node routing table entries in nodes D and E are marked as INOP for traffic flowing in the direction toward the failure.

Note: When a routing table entry becomes INOP in both directions, the entry is deleted from the table. In this case the node has become isolated by failure on each side somewhere along the route, and routing table entries are not needed for later ROUTE ELEMENT OPERATIVE notification. In this case, Node C deletes its routing table entry, and only nodes B and D transmit a ROUTE ELEMENT OP message to the route endpoint.

CASE 3: DISCOVERY OF AN INOPERATIVE ELEMENT DURING A ROUTE-SETUP ATTEMPT

This case is similar to Case 1 processing except that rather than a ROUTE-FAILURE notification being issued on the existing route, the failure notification becomes part of the ROUTE-SETUP failure notification. As in Case 1, the element in the topology data base which stopped the ROUTE-SETUP attempt is marked INOP. When the inoperative element becomes operative, then the same processing as described in Case 1 items (e) and (f) is done.

CASE 4: FAILURE OF A RESOURCE AFTER A ROUTE-SETUP MESSAGE HAS PASSED THE JUST FAILED ELEMENT

This case is similar to Case 1 except that failure notification is for a pending-active node routing table entry (since ROUTE-SETUP-REPLY has not been received) instead of for a fully-activated entry. Processing is the same for the adjacent node detecting the failure. The notification that the failed element has become operative occurs as stated in Case 1 items (e) and (f).

The above protocols may be implemented, as mentioned previously, in virtually any dynamic routing network to effect the principles of the preferred embodiment of the present invention. Additional standard

expedients may be added as desired, for example, implementation of message codes, operator status inquiry commands for routing table entry values, and the like.

HANDLING OF FULL ROUTING TABLES IN NETWORK NODES

5

During network operation one or more network nodes might have their routing tables filled to capacity, such that no further routing entries can be made in those nodes until the condition is alleviated. The normal way for such alleviation to occur is for sessions to end and for routes that are no longer being used to be deleted from the network. It may also be desirable to have a topology data base intervene automatically to delete route segments that are awaiting the reactivation or recovery of some resource, or to have a network operator request a topology data base to perform such an intervention.

Accordingly, it is possible to incorporate notification to a topology data base of the occurrence of a routing table condition of "full" in a network node. The network node sends a message indicating the full routing table condition to its controlling node, which in turn passes the message to the topology data base in that controlling node. The topology data base either cancels outstanding route requests involving the affected node or requests manual intervention by the network operator in making the decision, depending on initial settings in the topology data base. In the former case, notification to the network operator may be given even though no operator decision is necessary.

If the topology data base itself or the network operator decides to remove pending route requests from the network, the topology data base sends the appropriate ROUTE_DELETE request(s) along the established route segment(s) to delete those entries from the routing tables of the nodes in the route segment.

REMOVAL OF NODES FROM THE NETWORK

25

A network operator can decide to temporarily or permanently remove a link or node from the network. Such a link or node resource might be currently active or might be awaiting reactivation or recovery from an earlier failure. Accordingly, an operator command to the topology data base may be included to remove the representation of a resource from the network.

30

If the resource is active, user sessions dependent on the resource may be terminated or allowed to end normally, after which routes that include the resource are deleted in the normal manner by ROUTE_DELETE requests from a topology data base. After receiving a command to remove a resource in new ROUTE_SETUP requests.

35

If a link or node resource is awaiting reactivation or recovery when it is removed from the network, pending route requests dependent on the resource are cancelled. After receiving a command to remove a resource from the network, the topology data base issues ROUTE_DELETE requests for all pending route requests involving the removed resource and does not attempt to establish any new routes using that resource.

40

The present invention, as illustrated by the above description of embodiments thereof, provides a system for notifying a network topology data base of the availability of potential communication among the various elements of a communication network with greatly reduced network traffic as compared with prior art approaches. The considerable proliferation of status messages in the network is greatly reduced by the application of the present invention, and a minimal but sufficient class of nodes is given necessary availability information to create session routes efficiently and with a minimum of unnecessary utilisation of network resources.

45

Claims

50

1. A digital data message transmission network comprising nodes (12, 14, 16, 18, 20) connected by links (32, 34, 36, 40, 44), wherein a message travels between a source node and a destination node along a route comprising a sequence of nodes and connecting links, said network including means for maintaining a topology data base (112) recording the potentially available communication routes through the network and the status of the network nodes and links; each node being adapted to maintain a routing table and:
 - when acting as a source node, obtain a route from the topology database and send a ROUTE SET-UP message along the route to thereby establish the route;
 - respond to a ROUTE SET-UP message by recording an entry in its routing table with the identity of the route and the links and/or nodes therein that are immediately adjacent to that particular node;

55

said network being characterised in that each node is further adapted to:

detect any failure of an immediately adjacent node or link in the route either whilst attempting to establish the route or after the route has been established, and in response thereto (i) record the status of the route as inoperative in the respective entry in the node's routing table, said entry remaining substantially intact; and (ii) transmit a ROUTE FAILURE message identifying the failed node or link along the route in the opposite direction to the failed node or link;

respond to a ROUTE FAILURE message by (i) forwarding said ROUTE FAILURE message along the route in said opposite direction; and by

(ii) further recording the status of the route as inoperative in the respective entry in the node's routing table, said entry remaining substantially intact; and

when acting as a source or destination node, additionally forward said ROUTE FAILURE message to the topology data base for updating the recorded status of the network nodes and links.

2. A network as claimed in claim 1, wherein each node is adapted, when detecting the return to availability of an immediately adjacent node or link, to generate a ROUTE ELEMENT OPERATIVE message so indicating which is handled in the same manner as a ROUTE FAILURE message.

3. A network as claimed in claim 2, wherein there are three available status types for each network node or link in the topology data base, OPERATIVE, INOPERATIVE and UNKNOWN/(ASSUMED OPERATIVE), the default status being UNKNOWN, which status is switched to the appropriate other status in response to ROUTE FAILURE and ROUTE ELEMENT OPERATIVE messages.

4. A network as claimed in any preceding claim, wherein the topology data base stores information regarding the characteristics of the network nodes and links, and a source node sends a ROUTE REQUEST message specifying the source node identity, the destination node identity and the desired route characteristics, to the topology data base, which in response to such a message determines a "best-fit" operative route, and generates a corresponding ROUTE-SETUP message, defining the selected route identity and route elements in order.

5. A method of controlling a digital data message transmission network comprising nodes (12, 14, 16, 18, 20) connected by links (32, 34, 36, 40, 44), wherein a message travels between a source node and a destination node along a route comprising a sequence of nodes and connecting links, said network including means for maintaining a topology data base (112) recording the potentially available communication routes through the network and the status of the network nodes and links, each node being adapted to maintain a routing table;

said method comprising the steps of:

a source node obtaining a route from the topology database and sending a ROUTE SET-UP message along the route to thereby establish the route;

each node responding to a ROUTE SET-UP message by recording an entry in its routing table with the identity of the route and the links and/or nodes therein that are immediately adjacent to that particular node;

said method being characterised by further comprising the steps of:

each node detecting any failure of an immediately adjacent node or link in the route either whilst attempting to establish the route or after the route has been established, and in response thereto (i) recording the status of the route as inoperative in the respective entry in the node's routing table, said entry remaining substantially intact; and (ii) transmitting a ROUTE FAILURE message identifying the failed node or link along the route in the opposite direction to the failed node or link;

each node responding to a ROUTE FAILURE message by (i) forwarding said ROUTE FAILURE message along the route in said opposite direction; and by

(ii) further recording the status of the route as inoperative in the respective entry in the node's routing table, said entry remaining substantially intact; and

the source node and/or destination node additionally forwarding said ROUTE FAILURE message to the topology data base for updating the recorded status of the network nodes and links.

55 Patentansprüche

1. Übertragungsnetzwerk für digitale Datennachrichten, umfassend Knoten (12,14,16,18,20), die durch Verbindungsstrecken (32,34,36,40,44,) gekoppelt sind, bei dem eine Nachricht zwischen einem Quel-

- lenknoten und einem Zielknoten längs eines Leitweges läuft, der eine Folge von Knoten und gekoppelten Verbindungsstrecken umfaßt, und das Netzwerk Mittel zur Wartung einer Topologie-Datenbank (112) einschließt, die die möglichen verfügbaren Nachrichtenverbindungs-Leitwege durch das Netzwerk und den Status der Netzwerknoten und Verbindungsstrecken aufzeichnet,
- 5 wobei jeder Knoten eingerichtet ist, um eine Leitwegtabelle zu warten und, :
- wenn er als Quellenknoten dient, einen Leitweg von der Topologie-Datenbank zu erhalten und eine Nachricht LEITWEG AUFBAUEN längs des Leitweges zu schicken, um dadurch den Leitweg festzulegen,
- 10 auf eine Nachricht LEITWEG AUFBAUEN durch Aufzeichnen eines Eintrags in seine Leitwerttabelle mit der Identifizierung des Leitweges und der Verbindungsstrecken und/oder Knoten darin, die dem betreffenden Knoten unmittelbar benachbart sind, zu antworten,
- wobei das Netzwerk dadurch gekennzeichnet ist, daß jeder Knoten außerdem eingerichtet ist, um :
- jeden Fehler eines unmittelbar benachbarten Knotens oder einer Verbindungsstrecke in dem Leitweg festzustellen,
- 15 entweder während des Versuchs, einen Leitweg festzulegen, oder nachdem der Leitweg festgelegt wurde, und als Antwort darauf (i) den Status des Leitweges als funktionsunfähig in dem entsprechenden Eintrag in der Leitwegtabelle des Knotens aufzuzeichnen, wobei der Eintrag im wesentlichen unversehrt bleibt, und (ii) eine Nachricht LEITWEGFEHLER, die den fehlerhaften Knoten oder die fehlerhafte Verbindungsstrecke identifiziert, längs des Leitweges in der zu dem fehlerhaften Knoten oder der fehlerhaften Verbindungsstrecke entgegengesetzten Richtung zu übertragen, auf eine Nachricht LEITWEGFEHLER durch Übermitteln der Nachricht LEITWEGFEHLER längs des Leitweges in entgegengesetzter Richtung und durch (ii) weiteres Aufzeichnen des Status des Leitweges als funktionsunfähig in dem entsprechenden Eintrag in der Leitwegtabelle des Knotens zu antworten, wobei der Eintrag im wesentlichen unversehrt bleibt, und, wenn er als Quellen- oder Zielknoten arbeitet, zusätzlich die
- 20 Nachricht LEITWEGFEHLER zu der Topologie-Datenbank zu übertragen, um den aufgezeichneten Status der Knoten und Verbindungsstrecken des Netzwerkes auf den neuesten Stand zu bringen.
2. Netzwerk nach Anspruch 1, bei dem jeder Knoten dafür eingerichtet ist, wenn er die Rückkehr zur Verfügbarkeit eines unmittelbar benachbarten Knotens oder einer Verbindungsstrecke feststellt, eine
- 30 Nachricht LEITWEGELEMENT FUNKTIONSFÄHIG zu erzeugen, die das anzeigt, welche in der gleichen Weise behandelt wird wie die Nachricht LEITWEGFEHLER.
3. Netzwerk nach Anspruch 2, bei dem es drei gültige Statusarten für jeden Netzwerknoten oder jede Verbindungsstrecke in der Topologie-Datenbank gibt, FUNKTIONSFÄHIG, FUNKTIONSFÄHIG und UNBEKANNT / (ALS FUNKTIONSFÄHIG ANGENOMMEN), wobei der Vorgabezustand UNBEKANNT
- 35 ist, welcher Status zu dem geeigneten anderen Status als Antwort auf die Nachrichten LEITWEGFEHLER und LEITWEGELEMENT FUNKTIONSTÜCHTIG umgeschaltet wird.
4. Netzwerk nach irgendeinem vorhergehenden Anspruch, bei dem die Topologie-Datenbank Informationen bezüglich der Eigenschaften der Netzwerknoten und Verbindungsstrecken speichert, und ein Quellenknoten eine Nachricht LEITWEGANFORDERUNG, die die Identifizierung des Quellenknotens, die Identifizierung des Zielknotens und die gewünschten Leitwegeigenschaften angibt, an die Topologie-Datenbank abschickt, welche als Antwort auf solch eine Nachricht einen "am besten geeigneten" funktionstüchtigen Leitweg bestimmt und eine entsprechende Nachricht LEITWEG AUFBAUEN erzeugt,
- 40 die die ausgewählte Leitwegidentifizierung und die Leitwegelemente der Reihe nach bestimmt.
5. Verfahren zum Steuern eines Übertragungsnetzwerkes für digitale Datennachrichten, umfassend Knoten (12,14,16,18,20), die durch Verbindungsstrecken (32,34,36,40,44) gekoppelt sind, in dem eine Nachricht zwischen einem Quellenknoten und einem Zielknoten längs eines Leitweges läuft, der eine Folge von Knoten und koppelnden Verbindungsstrecken aufweist, wobei das Netzwerk Mittel zur Wartung einer
- 50 Topologie Datenbank (112) zum Aufzeichnen der möglichen verfügbaren Nachrichtenverbindungs-Leitwege durch das Netzwerk und des Status der Netzwerknoten und Verbindungsstrecken einschließt, und jeder Knoten eingerichtet ist, um eine Leitwegtabelle zu warten,
- wobei das Verfahren die Schritte umfaßt,:
- 55 daß ein Quellenknoten einen Leitweg von der Technologie-Datenbank erhält und eine Nachricht LEITWEG FESTLEGEN längs eines Leitweges sendet, um dadurch den Leitweg festzulegen, daß jeder Knoten auf eine Nachricht LEITWEG FESTLEGEN durch Aufzeichnen eines Eintrags in seine Leitwegtabelle mit dem Identifizieren des Leitweges und der Verbindungsstrecken und/oder Knoten darin, die

unmittelbar zu dem betreffenden Knoten benachbart sind, antwortet,
wobei das Verfahren dadurch gekennzeichnet ist, daß es weiter die Schritte umfaßt, daß:
jeder Knoten jeden Fehler eines unmittelbar benachbarten Knotens oder einer Verbindungsstrecke in
dem Leitweg feststellt, entweder beim Versuch, den Leitweg festzulegen, oder nachdem der Leitweg
festgelegt wurde, und als Antwort darauf (i) den Status des Leitweges als funktionsunfähig in dem
betreffenden Eintrag in der Leitwegtabelle des Knotens aufzeichnet, wobei der Eintrag im wesentlichen
unversehrt bleibt, und (ii) eine Nachricht LEITWEGFEHLER, die den fehlerhaften Knoten oder die
fehlerhafte Verbindungsstrecke identifiziert, längs des Leitweges in der zum fehlerhaften Knoten oder
zur fehlerhaften Verbindungsstrecke entgegengesetzten Richtung überträgt,
wobei jeder Knoten auf eine Nachricht LEITWEGFEHLER durch Absenden der Nachricht LEITWEG-
FEHLER längs des Leitweges in der entgegengesetzten Richtung und ferner durch (ii) Aufzeichnen des
Status des Leitweges als funktionsunfähig in den entsprechenden Eintrag in der Leitwegtabelle des
Knotens antwortet, wobei der Eintrag im wesentlichen unversehrt bleibt und der Quellenknoten und/oder
der Zielknoten zusätzlich die Nachricht LEITWEGFEHLER an die Topologie-Datenbank abschickt, um
den aufgezeichneten Zustand der Netzwerknoten und Verbindungsstrecken auf den neuesten Stand zu
bringen.

Revendications

1. Un réseau de transmission des messages de données numériques comprenant des noeuds (12, 14, 16, 18, 20) connectés par des liaisons (32, 34, 36, 40, 44), et dans lequel un message circule entre un noeud source et un noeud destination, suivant un itinéraire comportant une suite de noeuds et de liaisons, ledit réseau incorporant des moyens de maintenance d'une base de données topologique (112), enregistrant les itinéraires de communication potentiellement disponibles au travers du réseau, ainsi que l'état des noeuds et liaisons du réseau ;
chaque noeud permettant la gestion d'une table de routage et :
pour obtenir, lorsque ledit noeud agit comme un noeud source, un itinéraire en provenance de la base de données topologique, et transmettre un message ROUTE SET-UP (paramétrage d'itinéraire) sur ledit itinéraire de façon à établir ledit itinéraire ;
et réagir au message ROUTE SET-UP, par l'enregistrement d'une entrée dans sa table de routage, ladite entrée comportant l'identité de l'itinéraire et les liaisons et/ou noeuds dudit itinéraire, qui sont immédiatement adjacents à ce noeud particulier ;
ledit réseau étant caractérisé en ce que chaque noeud permet, en outre :
la détection de toute panne d'une liaison ou d'un noeud immédiatement adjacent, dans l'itinéraire, soit pendant la tentative de définition de l'itinéraire, soit une fois que l'itinéraire a été établi et, en réaction à ladite panne (i) d'une part, l'enregistrement de l'état de l'itinéraire en tant qu'inopérant, dans l'entrée correspondante de la table de routage du noeud (ladite entrée demeurant substantiellement intacte), et, d'autre part (ii), la transmission d'un message ROUTE FAILURE (panne d'itinéraire) identifiant la liaison ou le noeud défectueux, sur l'itinéraire, ladite transmission s'effectuant dans le sens opposé à la liaison ou au noeud défectueux ;
la réaction à un message ROUTE FAILURE (i) par l'émission dudit message ROUTE FAILURE le long dudit itinéraire, dans ledit sens opposé et (ii) par l'enregistrement de l'état de l'itinéraire en tant qu'inopérant, dans l'entrée correspondante de la table de routage du noeud (ladite entrée demeurant essentiellement intacte) ; et
la transmission complémentaire, lorsque ledit noeud agit comme noeud source ou destination, dudit message ROUTE FAILURE à la base de données topologique, afin de mettre à jour l'état enregistré des noeuds et liaisons du réseau.
2. Un réseau, conformément à la revendication 1, où chaque noeud permet, lors de la détection du retour à l'état de disponibilité d'une liaison ou d'un noeud immédiatement adjacent, la génération d'un message ROUTE ELEMENT OPERATIVE (élément d'itinéraire opérationnel), indiquant l'état opérationnel, et géré de la même manière qu'un message ROUTE FAILURE.
3. Un réseau, conformément à la revendication 2, où il existe trois types disponibles d'état pour chaque noeud ou liaison du réseau, dans la base de données topologique, à savoir les états OPERATIVE (opérationnel), INOPERATIVE (inopérant) et UNKNOWN/(ASSUMED OPERATIVE) (inconnu/(présumé opérationnel)), l'état par défaut étant l'état UNKNOWN, et dont l'état est basculé sur l'autre état éventuel approprié, en réponse aux messages ROUTE FAILURE et ROUTE ELEMENT OPERATIVE.

4. Un réseau, conformément à toutes les revendications précédentes, où la base de données topologique sauvegarde les informations concernant les caractéristiques des noeuds et liaisons du réseau, et où un noeud source envoie un message ROUTE REQUEST (demande d'itinéraire) spécifiant l'identité d'une source, l'identité du noeud destination et les caractéristiques de l'itinéraire souhaité, à destination de la base de données topologique qui, en réponse à un tel message, détermine l'itinéraire opérationnel le mieux adapté et génère un message ROUTE-SETUP (paramétrage d'itinéraire) correspondant, définissant l'identité de l'itinéraire sélectionné et les éléments de l'itinéraire dans l'ordre.
5. Une méthode de gestion d'un réseau de transmission des messages de données numériques comprenant des noeuds (12, 14, 16, 18, 20) connectés par des liaisons (32, 34, 36, 40, 44), où un message circule entre un noeud source et un noeud destination, suivant un itinéraire comprenant une série de noeuds et de liaisons de connexion ledit réseau incorporant des moyens de maintenance d'une base de données topologique (112), enregistrant les itinéraires de communication potentiellement disponibles au travers du réseau, ainsi que l'état des noeuds et liaisons du réseau, chaque noeud permettant la gestion d'une table de routage ; ladite méthode intégrant diverses étapes : un noeud source obtenant un itinéraire délivré par la base de données topologique et transmettant un message ROUTE SET-UP par ledit itinéraire, de manière à ainsi établir ledit itinéraire ; chaque noeud réagissant à un message ROUTE SET-UP par l'enregistrement d'une entrée dans sa table de routage, ledit enregistrement comportant l'identité de l'itinéraire et des liaisons et/ou noeuds concernés, qui sont immédiatement adjacents à ce noeud particulier ; ladite méthode étant caractérisée en ce qu'elle comprend, en outre, les étapes suivantes : chaque noeud détectant une quelconque panne d'une liaison ou d'un noeud immédiatement adjacent dans l'itinéraire soit pendant la tentative de définition de l'itinéraire, soit une fois que l'itinéraire a été établi et, en réaction à ladite panne, d'une part (i) à l'enregistrement de l'état de l'itinéraire en tant qu'inopérant, dans l'entrée correspondante de la table de routage du noeud (ladite entrée demeurant substantiellement intacte), et, d'autre part (ii), à la transmission d'un message ROUTE FAILURE (panne d'itinéraire) identifiant la liaison ou le noeud défectueux, sur l'itinéraire, ladite transmission s'effectuant dans le sens opposé à la liaison ou au noeud défectueux ; chaque noeud répondant à un message ROUTE FAILURE (i) par l'émission dudit message ROUTE FAILURE le long dudit itinéraire, dans ledit sens opposé et, (ii) par l'enregistrement de l'état de l'itinéraire en tant qu'inopérant, dans l'entrée correspondante de la table de routage du noeud (ladite entrée demeurant essentiellement intacte) ; et le noeud source et/ou le noeud destination transmettant, en outre, ledit message ROUTE FAILURE à la base de données topologique afin de mettre à jour l'état enregistré des noeuds et liaisons du réseau.
